User Stories

As a budget-conscious shopper, I want to compare prices for the same item across different stores so I can find the best deal.

- 15 points
- Quick Shop's core value is price comparison. To implement this, each item search will aggregate listings from multiple retailers and group them under a shared product search. Price, store, delivery, and availability info will be displayed side by side. This requires backend support to normalize and deduplicate incoming data, likely using a shared product ID system.
- Testing will involve searching for identical items across stores and verifying correct grouping, price accuracy, and store representation

---

As a casual shopper, I want to search by keyword or category so I can easily find the type of product I'm looking for.

- 5 points
- Quick Shop will allow users to enter keywords or select categories (e.g., "snacks" or "orange juice") to retrieve relevant listings. Each search triggers a query against multiple store APIs or data scrapers, returning grouped product results.
- Testing will confirm the ability to search by keyword, match grouped identities, and return products with accurate metadata.

As a picky shopper, I want to filter and sort my results so I can narrow down to what I actually want.

- 8 points
- Users will be able to apply filters such as brand, price range, dietary tags, and store. They can also sort by relevance, price, or delivery time. This is done on grouped product listings rather than individual entries.
- Testing will involve applying filters and sort orders, confirming result updates and proper groupings.

As a user, I want to add a specific retailer's item to my cart so I can build a multi-store order.

- 5 points
- The "Add to Cart" button is shown for each listing under a product group. When clicked, the cart stores the item with its retailer and price.
- Testing will ensure the item added is correctly tied to the chosen retailer and is not replaced by other store versions.

As a user, I want to update or remove items in my cart so I can finalize my selections.

- 3 point
- Users can remove items, adjust quantities, or switch retailers for a grouped product by re-selecting a different listing.
- Testing will confirm that updates persist, totals recalculate, and the cart remains valid for checkout.

As a shopper ready to purchase, I want to be redirected to the correct retailer site when I check out so I can buy with confidence.

- 8 points
- Quick Shop provides a “Buy from [Retailer]” button per store group. Clicking this opens the corresponding site and preloads the product if the retailer supports deep links.
- Testing will involve verifying link accuracy, cart-to-store matching, and graceful handling of unsupported cases.

As a busy user, I want to save items for later so I don’t lose track of products I’m considering.

- 3 points
- Each listing will include a “Save for Later” button that stores the item (and associated retailer) in a separate list accessible from the cart.
- Testing will verify saved item persistence, visibility across sessions, and ability to move items back into the cart.

As a returning user, I want my cart and saved items to persist between sessions so I don’t have to redo everything.

- 6 point
- Quick Shop will store cart and saved item data in local storage or user accounts.
- Testing will cover reloading, logging in/out (if we do have accounts), and resuming sessions with items intact.

As a budget-conscious shopper, I want to compare prices in the cart between multiple retailers for the same item, so I can switch to a cheaper option if available.

- 6 point

- Quick Shop will allow users to view alternate listings (from different retailers) for each item already in the cart. Users can then choose to replace the current cart item with a lower-priced or faster-delivery alternative.
- Testing will involve adding an item to the cart, triggering comparison suggestions, switching between retailers, and verifying the cart updates correctly without duplication.
